ARISING FROM C. P. Carmona et al. *Nature* <https://doi.org/10.1038/s41586-021-03871-y> (2021)

Two recent publications^{1,2} have explored the importance of roots for understanding plant form and function, but reached opposite conclusions on the basis of largely overlapping data. Carmona et al.¹ concluded that their results “do not confirm the strong covariation between leaf and fine-root traits predicted by the plant economics spectrum hypothesis”. By contrast, Weigelt et al.² concluded that “key leaf and fine-root traits were aligned along the expected [fast–slow] ‘conservation’ gradient of plant economic investment”. Here we reflect on the causes for the apparent discrepancies of these studies and show that the rationale behind trait selection is vital for the conclusions.

In his ‘traits manifesto’, Reich³ hypothesized that strong selection along trait trade-offs must result in convergence for any taxon on a uniformly fast, medium or slow strategy for all organs (leaves, stems and roots) and all resources (carbon, nitrogen and water). This proposed alignment of multiple organ strategies also seems inevitable for stoichiometric reasons: fast carbon fixation in leaves without high nitrogen uptake rates in roots would result in low plant nitrogen concentration which would reduce carbon fixation per unit leaf mass⁴. However, Carmona et al. conclude from their results that aboveground and root trait planes are decoupled¹. Like Carmona et al., Weigelt et al. found a unique trait axis with root diameter and specific root length distinct from aboveground traits. However, Weigelt et al. also found consistent alignment of leaf and root nitrogen content, as well as leaf mass per area and root tissue density².

Indeed, in Fig. 1 in Carmona et al., it seems as if “four dimensions [are] needed to explain the non-redundant information in the dataset [which] can be summarized in an aboveground and a fine-root plane”¹. However, their correlation coefficient of leaf nitrogen to root nitrogen content (301 species, Extended Data Fig. 1 in ref. 1) is strongly positive with $r = 0.37$. This value (and most other pairwise correlation coefficients in ref. 1) are similar to those in Weigelt et al. (that is, $r = 0.38$ for leaf versus root nitrogen, 1,394 species (fig. S2 in ref. 2)). In addition, the positive correlation between leaf and root nitrogen is supported by a wealth of published studies (fig. 2 in ref. 2 and fig. 2 in ref. 5). Although the principal components analysis (PCA) plots of the two studies appear different, the underlying correlation coefficients are not, suggesting that the claim by Carmona et al. that aboveground and fine-root trait

spaces are decoupled is to some extent unsupported. Here we expand on our thoughts regarding two potential causes for these apparent differences—trait selection and varimax rotation.

Carmona et al. draw conclusions on a comparison among aboveground and belowground traits, on the basis of six aboveground traits spanning a wide spectrum of plant form and function⁶ and four fine-root traits linked to resource acquisition—conservation functions⁷. Notably, Carmona et al. included aboveground traits that are not directly related to resource acquisition, including stem specific density, plant height and seed mass¹. In turn, Weigelt et al. used a stepwise approach (fig. 1 in ref. 2) to first compare traits that are proposed to be functionally relevant, and then increased complexity with additional traits not directly related to resource acquisition. This means that Weigelt et al. first compared functionally analogous leaf and root traits exclusively related to resource investment (leaf and root nitrogen, leaf mass per area, root tissue density, specific root length and root diameter (fig. 3 in ref. 2)), and found significant correlations. Weigelt et al. subsequently included size-related traits (plant height and rooting depth), which yielded two additional trait gradients loading independently on principal component axes 3 and 4.

To substantiate the importance of trait selection, we reanalysed the 301 species used by Carmona et al. with these six traits, equally representing aboveground and belowground aspects of plant form and function (Fig. 1a). By selecting the same traits in a PCA, we observed a correlation between the leaf and root trait spaces, similar to Weigelt et al. Stepwise inclusion of size-related traits (Fig. 1b) and seed mass (Fig. 1c) then changed the interpretation of the study results. Our reanalysis shows that the rationale leading to the trait selection is a critical factor in such studies. The apparent discrepancies in conclusions between the two studies seem to be triggered primarily by the presence or absence of seed mass, a reproductive trait spanning a large range of variation that might mask the more subtle changes in acquisitive traits. Our stepwise analysis (Fig. 1a–c) reconfirms that results of multivariate analyses depend on the type and number of traits included. We argue that trait selection requires careful ecological consideration and should be based on knowledge of trait functionality.

A related point of concern is the claim by Carmona et al. that trait variation is greater aboveground than belowground, as they find “greater

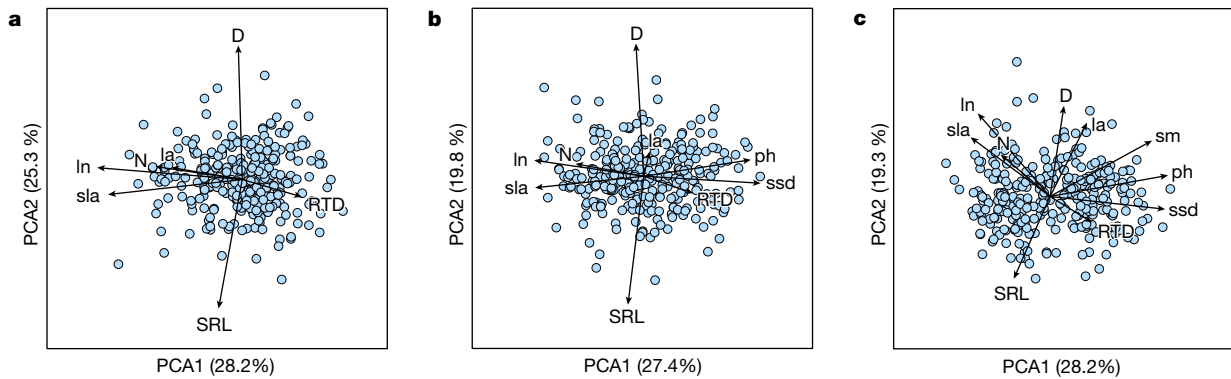

Fig. 1 | PCA of the 301 species analysed in Carmona et al.¹ using differing trait subsets and no varimax rotation. **a**, Traits strictly related to resource acquisition aboveground (leaf nitrogen content (In), leaf area (la) and specific leaf area (sla)) and belowground (root nitrogen content (N), root tissue density (RTD), root diameter (D) and specific root length (SRL)) show strong

aboveground–belowground correlation, as in Weigelt et al.². **b**, Addition of stem traits (plant height (ph) and stem specific density (ssd)). **c**, Inclusion of seed mass (sm), without strong aboveground and belowground correlation as in ref. 1. Details are shown in Supplementary Table 1.

differentiation in aboveground trait syndromes than in fine roots [...]¹. We expect that this outcome is again related primarily to their aboveground trait selection, which encompasses a wider trait gradient for potential variation than the selected belowground traits. Carmona et al. acknowledge this in the article, but the overall conclusion still hints at a systematic difference in trait variation aboveground compared with belowground. Here we caution against such a generalization on the basis of statistical inference rather than biological understanding.

A second cause for the differences in PCAs could be that Carmona et al. use a varimax rotation of the PCA axes, whereas Weigelt et al. do not. Theoretically, this rotation should not change the outcome of the analysis, but should improve the interpretability as individual traits are better aligned with the main axes⁸. However, PCA axes after varimax rotation may not perfectly reflect the position of the original variables. As a result, although rotated PCA axes remain orthogonal, the representation of underlying variables may not⁹. This seems to be the case in Carmona et al., where the high correlation of leaf nitrogen and root nitrogen with the axis representing the leaf economics spectrum (PCA2; loadings 0.44 and 0.31 for leaf and root nitrogen, respectively) disappears for root nitrogen after varimax rotation (loadings 0.59 and 0.08 for leaf and root nitrogen, respectively (Extended Data Table 2 in ref. 1)). Similarly, there are clear differences in primary trait association with the second and third axes between the rotated and unrotated analysis for 301 species. Notably, the full decoupling between root and leaf traits is visible only in the rotated form. However, we note that root traits linked to the conservation gradient¹⁰ (root tissue density and root nitrogen) also load to other principal component axes, irrespective of axis rotation^{1,2}, indicating flexibility in the biological coordination of these traits.

Despite our concerns regarding some of the conclusions of Carmona et al., we admire the extent and depth of data and analyses provided. As plant ecologists, we all wish to improve our understanding and quantification of plant trait variation, and particularly belowground plant traits, which have lagged behind their showier aboveground counterparts^{11–13}. Progress will be built on critical and open conversations on the role of both known and unknown functions of aboveground and belowground plant traits. A better functional understanding of traits above and belowground will improve our understanding of the role of plant traits in shaping the responses of plant communities and ecosystems in a rapidly changing world.

Reporting Summary

Nature Portfolio wishes to improve the reproducibility of the work that we publish. This form provides structure for consistency and transparency in reporting. For further information on Nature Portfolio policies, see our [Editorial Policies](#) and the [Editorial Policy Checklist](#).

Statistics

For all statistical analyses, confirm that the following items are present in the figure legend, table legend, main text, or Methods section.

n/a | Confirmed

- The exact sample size (n) for each experimental group/condition, given as a discrete number and unit of measurement
- A statement on whether measurements were taken from distinct samples or whether the same sample was measured repeatedly
- The statistical test(s) used AND whether they are one- or two-sided
Only common tests should be described solely by name; describe more complex techniques in the Methods section.
- A description of all covariates tested
- A description of any assumptions or corrections, such as tests of normality and adjustment for multiple comparisons
- A full description of the statistical parameters including central tendency (e.g. means) or other basic estimates (e.g. regression coefficient) AND variation (e.g. standard deviation) or associated estimates of uncertainty (e.g. confidence intervals)
- For null hypothesis testing, the test statistic (e.g. F , t , r) with confidence intervals, effect sizes, degrees of freedom and P value noted
Give P values as exact values whenever suitable.
- For Bayesian analysis, information on the choice of priors and Markov chain Monte Carlo settings
- For hierarchical and complex designs, identification of the appropriate level for tests and full reporting of outcomes
- Estimates of effect sizes (e.g. Cohen's d , Pearson's r), indicating how they were calculated

Our web collection on [statistics for biologists](#) contains articles on many of the points above.

Software and code

Data collection

Data analysis

For manuscripts utilizing custom algorithms or software that are central to the research but not yet described in published literature, software must be made available to editors and reviewers. We strongly encourage code deposition in a community repository (e.g. GitHub). See the Nature Portfolio [guidelines for submitting code & software](#) for further information.

Data

Policy information about [availability of data](#)

All manuscripts must include a [data availability statement](#). This statement should provide the following information, where applicable:

- Accession codes, unique identifiers, or web links for publicly available datasets
- A description of any restrictions on data availability
- For clinical datasets or third party data, please ensure that the statement adheres to our [policy](#)

All data is available as indicated in the paper Carmona et al. 2021 Nature. Specifically, the data is in the Figshare repository: <https://doi.org/10.6084/m9.figshare.13140146>.

Research involving human participants, their data, or biological material

Policy information about studies with [human participants or human data](#). See also policy information about [sex, gender \(identity/presentation\), and sexual orientation](#) and [race, ethnicity and racism](#).

Reporting on sex and gender

Use the terms *sex* (biological attribute) and *gender* (shaped by social and cultural circumstances) carefully in order to avoid confusing both terms. Indicate if findings apply to only one sex or gender; describe whether sex and gender were considered in study design; whether sex and/or gender was determined based on self-reporting or assigned and methods used. Provide in the source data disaggregated sex and gender data, where this information has been collected, and if consent has been obtained for sharing of individual-level data; provide overall numbers in this Reporting Summary. Please state if this information has not been collected. Report sex- and gender-based analyses where performed, justify reasons for lack of sex- and gender-based analysis.

Reporting on race, ethnicity, or other socially relevant groupings

Please specify the socially constructed or socially relevant categorization variable(s) used in your manuscript and explain why they were used. Please note that such variables should not be used as proxies for other socially constructed/relevant variables (for example, race/ethnicity should not be used as a proxy for socioeconomic status). Provide clear definitions of the relevant terms used, how they were provided (by the participants/respondents, the researchers, or third parties), and the method(s) used to classify people into the different categories (e.g. self-report, census or administrative data, social media data, etc.) Please provide details about how you controlled for confounding variables in your analyses.

Population characteristics

Describe the covariate-relevant population characteristics of the human research participants (e.g. age, genotypic information, past and current diagnosis and treatment categories). If you filled out the behavioural & social sciences study design questions and have nothing to add here, write "See above."

Recruitment

Describe how participants were recruited. Outline any potential self-selection bias or other biases that may be present and how these are likely to impact results.

Ethics oversight

Identify the organization(s) that approved the study protocol.

Note that full information on the approval of the study protocol must also be provided in the manuscript.

Field-specific reporting

Please select the one below that is the best fit for your research. If you are not sure, read the appropriate sections before making your selection.

Life sciences Behavioural & social sciences Ecological, evolutionary & environmental sciences

REPLYING TO A. Weigelt et al. *Nature* <https://doi.org/10.1038/s41586-023-06148-8> (2023)

In the accompanying Comment¹, Weigelt et al. (2023) claim that the different conclusions of two studies—Weigelt et al. (2021)² and Carmona et al. (2021)³—presenting global integrations of aboveground and belowground plant traits are due to methodological issues in Carmona et al. Specifically, ref. 2 concluded that leaf and fine-root traits are coordinated, whereas ref. 3 reported weak covariation between these traits. In their Comment, Weigelt et al. attribute these divergent conclusions to the selection of traits and the use of varimax rotation in ref. 3. Here we estimate angles between pairs of traits in different functional spaces to show that these objections are not supported by the data.

The two studies analysed the same data using principal components analysis (PCA) to determine the necessary dimensions for explaining non-redundant plant trait information. Although we appreciate the points raised in the Comment, we found inconsistencies in the arguments and analyses. For example, consider the relationship between leaf nitrogen content (ln) and root nitrogen content (N). Weigelt et al. view these traits as having “a strong positive correlation coefficient” ($r = 0.37$), supporting Reich’s plant economics spectrum hypothesis⁴, which predicts coordination between ln and N. Although the arguments behind the hypothesis are strong, empirical support for it is mixed^{5–11}, which prompted us to test it against the most comprehensive trait dataset³. If two traits are highly coordinated, knowing the value of one we could precisely estimate the value of the other. However, the common amount of variation in ln and N is low ($r^2 = 0.137$), so we maintain our original conclusion of no strong coordination between these traits³.

Characterizing the coordination between pairs of traits after selecting relevant principal components is more complex than analysing individual correlations, because all dimensions should be considered simultaneously. To better understand relationships between traits, we propose to consider the angle they form in the appropriate dimensionality of the space: highly coordinated traits should form a low angle, whereas independent traits should be nearly orthogonal (Fig. 1a and Supplementary information). We address the specific arguments in the Comment using this approach.

Weigelt et al.¹ consider that the space in Carmona et al.³ is inadequate for testing a single acquisition–conservation gradient across leaves and roots, arguing that seed mass is not related to resource acquisition. We included seed mass along with five other aboveground traits because our primary aim was to reveal patterns at the level of whole-plant form and function, rather than comparing fully analogous organs of resource acquisition³ (an important plant function, but not the only one). In the Comment, Weigelt et al. claim that the inclusion of seed mass distorts the estimated relationships between other traits. They base this claim

on a stepwise PCA analysis in which traits are included sequentially. Although the stepwise analysis seems reasonable, Weigelt et al. do not consider the appropriate dimensionalities when interpreting differences between consecutive PCAs (compare their Fig. 1 with their Supplementary Table 1 (ref. 1)). Instead, they interpret projections of three- and four-dimensional vectors in two-dimensional planes, reaching distorted interpretations of trait relationships. In Fig. 1b, we show how the relationship between ln and N can look very different when considering two dimensions versus three dimensions. Indeed, when all significant dimensions are considered in the sequential PCAs¹, the angles between traits strictly related to resource acquisition are essentially the same, regardless of whether size-related traits are considered or not (Fig. 2a). Therefore, the selection of traits in Carmona et al. did not alter ecological inference.

The Comment also question the finding of greater differentiation in aboveground traits than fine-root traits, without providing any supporting analysis. We stand by our conclusion from Carmona et al.³, which is supported by our analyses here. The mere order of PCA axes in Fig. 1 in Carmona et al.³ indicates that variation aboveground (axes 1 and 2) is larger than for fine-root traits (axes 3 and 4). Moreover, differentiation between families and biomes is higher for the traits and the component of space related to plant size (C1), followed by the component reflecting the leaf economics spectrum (C2) (Extended Data Fig. 1). Of note, fine-root traits and related components (C3 and C4) are those for which differentiation was smallest, even when individual traits were analysed.

In Carmona et al., we performed a PCA based on ten key aboveground and fine-root traits, finding four fundamental dimensions of variation. This PCA was followed by a varimax rotation of the four-dimensional space (original space) to enhance its interpretability (rotated space). Weigelt et al. argue¹ that the varimax rotation of the principal components distorts the relationship between traits. However, although the rotation results in different loadings between the original and rotated spaces, it should not change the relationship among traits (on which ecological inference should be based). By comparing the angles between traits in both the original and rotated spaces (Supplementary Information), we demonstrate that the relationships between traits are completely unaffected by the rotation (Fig. 2b). Therefore, rather than distorting inference, the use of varimax rotation helped Carmona et al. to identify the space configuration in which intrinsic differences between traits are most apparent, aiding their correct interpretation and ecological inference.

Weigelt et al. (2023) claim that despite using the same data, the results of refs. 2,3 are fundamentally different. Here we have used data from the

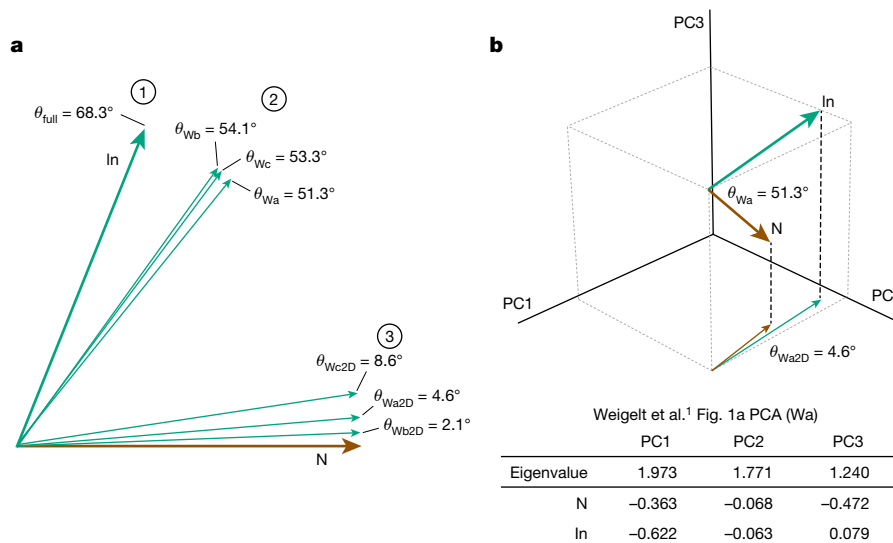

Fig. 1 | The effect of dimensionality reduction and trait selection on the In-N relationship. **a**, The relationship between leaf nitrogen (In) and root nitrogen (N) expressed as an angle θ , which is estimated considering different dimensionalities and accompanying traits. (1) Raw trait values (full PCA space). In geometric terms, the correlation coefficient between In and N (0.37) corresponds to (is the cosine of) the angle the two traits form in a full PCA space (that is, without dimensionality reduction; $\theta_{full} = 68.3^\circ$). (2) In the Comment¹, the data are fit to three PCAs, starting with only leaf and fine-root traits (Wa), and adding sequentially stem traits (Wb) and seed mass (Wc). The angle between In and N is similar in these three spaces when all significant dimensions (those

with eigenvalues greater than 1) are considered (θ_{Wa} , θ_{Wb} , θ_{Wc}), indicating that trait selection did not alter ecological inference. (3) When interpreting the relationship between traits, Weigelt et al. consider only projections of the traits in the first two components of their PCAs (see fig. 1 in ref. 1). This leads to large overestimations of the degree of coordination between In and N (θ_{Wa2D} , θ_{Wb2D} , θ_{Wc2D}). **b**, Unjustified reduction of dimensionality can lead to inferring misleading relationships between traits. The In-N relationship from the first PCA in ref. 1 (with three significant dimensions) differs strongly from the relationship when only two dimensions are considered.

phylogenetically informed PCA reported in Table S4 of ref. 2 to estimate the angles between all pairs of traits reported in the two studies and compared them. The results are remarkably similar in this analysis (the correlation between angles from both studies is 0.97; Fig. 2c), which means that the main difference between them lies in how the functional spaces are interpreted. In the Comment, projections for the first two components are used to explore a space of three dimensions, leading to the conclusion that some aboveground and fine-root traits—such

as In and N or specific leaf area and root tissue density—were aligned¹. However, when the appropriate dimensionalities are considered, In and N are not strongly aligned (Fig. 1b) in either of the studies^{2,3}, whereas specific leaf area and root tissue density are close to orthogonal (95 degrees; Fig. 2c).

A comprehensive understanding of the relationship among plant traits can only be achieved by considering all relevant dimensions. For this, examining the angles between traits is less prone to errors than

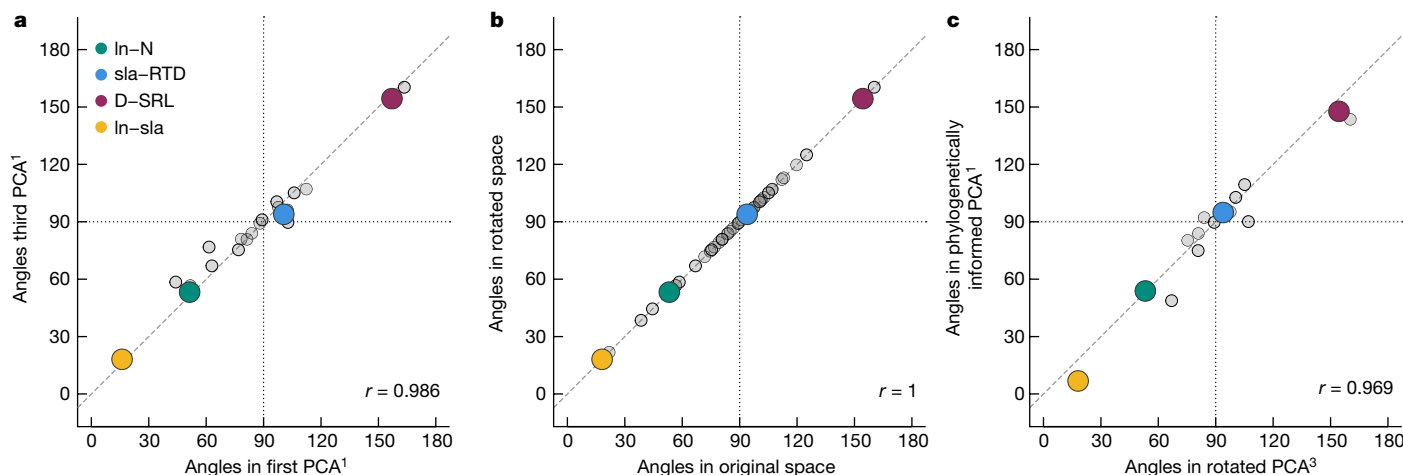

Fig. 2 | Rotation and trait selection do not affect trait relationships. **a**, The ‘first PCA’ (resource-acquisition traits) and ‘third PCA’ (all traits used in Carmona et al.) in the accompanying Comment¹ show almost identical angles between pairs of traits ($n = 21$; $r = 0.986$), refuting the idea that including ph, ssd and especially sm affects the relationships between resource-acquisition traits. **b**, The angles between all pairs of traits in the non-rotated PCA and varimax-rotated spaces from Carmona et al.² are identical, demonstrating that varimax

rotation has no effect on the inferred relationships. **c**, The angles between the common traits in the phylogenetically informed PCA in the Comment¹ and the rotated PCA in Carmona et al.³ are almost identical ($n = 15$; $r = 0.969$), indicating that Carmona et al.³ and Weigelt et al.^{1,2} arrived to different conclusions owing to different interpretations. The In-N (green) and sla-RTD (blue) pairs are closer to 90° than to 0° or 180° , indicating weak relationships. To facilitate comparison, four pairs of traits are displayed in different colours.

directly interpreting their loadings in PCA components; we recommend this approach to ecologists analysing multivariate trait spaces. The varimax rotation, rather than changing the characteristics of this space, can help to identify the perspective from which the genuine relationships among traits are most evident. On the basis of the available information, our results and reassessment of the results reported in Weigelt et al.² do not support the existence of a fast–slow conservation gradient at a global scale in which leaf and fine-root traits are aligned. Instead, we confirm that the aboveground and fine-root traits considered are not strongly correlated at a global scale, but rather organized in four main dimensions of functional variation reflecting differences in size, leaf economics, symbiosis and root tissue economics. Finally, we note that although we disagree on trait selection and data processing, the comprehensive analyses by Weigelt et al. undoubtedly advance plant trait research.

Matters arising

Extended Data Fig.1 | Larger differentiation in aboveground than fine-root traits. Proportion of variance explained in PERMANOVA analyses by differences among groups of species (families and biomes, see Carmona et al.³ for details), considering the whole functional space (Total), the aboveground and fine-root planes, individual components of the functional space and individual traits. This way, fine-root axes (C3 and C4) and traits (SRL, D, N and RTD), and leaf economics spectrum axis (C2) and traits (ln, la, sla) can be compared after removing the dominant effect of size (C1) and size-related traits (ph, sm, ssd)

on differences between groups of species. High values of explained variance mean that differences between the members of one group (e.g. differences between families) account for a large proportion of the total variance (in the total space, a specific plane, a specific component or a specific trait).

a. Differences between families in the functional space considering different scales: four-dimensional space (total), aboveground plane (in green) and fine-roots plane (in red), the individual components of the trait space (C1 to C4), and the individual traits. **b.** Differences between biomes.

Reporting Summary

Nature Portfolio wishes to improve the reproducibility of the work that we publish. This form provides structure for consistency and transparency in reporting. For further information on Nature Portfolio policies, see our [Editorial Policies](#) and the [Editorial Policy Checklist](#).

Statistics

For all statistical analyses, confirm that the following items are present in the figure legend, table legend, main text, or Methods section.

- | n/a | Confirmed |
|-------------------------------------|--|
| <input type="checkbox"/> | <input checked="" type="checkbox"/> The exact sample size (n) for each experimental group/condition, given as a discrete number and unit of measurement |
| <input type="checkbox"/> | <input checked="" type="checkbox"/> A statement on whether measurements were taken from distinct samples or whether the same sample was measured repeatedly |
| <input type="checkbox"/> | <input checked="" type="checkbox"/> The statistical test(s) used AND whether they are one- or two-sided
<i>Only common tests should be described solely by name; describe more complex techniques in the Methods section.</i> |
| <input type="checkbox"/> | <input checked="" type="checkbox"/> A description of all covariates tested |
| <input type="checkbox"/> | <input checked="" type="checkbox"/> A description of any assumptions or corrections, such as tests of normality and adjustment for multiple comparisons |
| <input type="checkbox"/> | <input checked="" type="checkbox"/> A full description of the statistical parameters including central tendency (e.g. means) or other basic estimates (e.g. regression coefficient) AND variation (e.g. standard deviation) or associated estimates of uncertainty (e.g. confidence intervals) |
| <input type="checkbox"/> | <input checked="" type="checkbox"/> For null hypothesis testing, the test statistic (e.g. F , t , r) with confidence intervals, effect sizes, degrees of freedom and P value noted
<i>Give P values as exact values whenever suitable.</i> |
| <input checked="" type="checkbox"/> | <input type="checkbox"/> For Bayesian analysis, information on the choice of priors and Markov chain Monte Carlo settings |
| <input checked="" type="checkbox"/> | <input type="checkbox"/> For hierarchical and complex designs, identification of the appropriate level for tests and full reporting of outcomes |
| <input type="checkbox"/> | <input checked="" type="checkbox"/> Estimates of effect sizes (e.g. Cohen's d , Pearson's r), indicating how they were calculated |

Software and code

Policy information about [availability of computer code](#)

Data collection

Data analysis

For manuscripts utilizing custom algorithms or software that are central to the research but not yet described in published literature, software must be made available to editors and reviewers. We strongly encourage code deposition in a community repository (e.g. GitHub). See the Nature Portfolio [guidelines for submitting code & software](#) for further information.

Data

Policy information about [availability of data](#)

All manuscripts must include a [data availability statement](#). This statement should provide the following information, where applicable:

- Accession codes, unique identifiers, or web links for publicly available datasets
- A description of any restrictions on data availability
- For clinical datasets or third party data, please ensure that the statement adheres to our [policy](#)

All the data used in this paper comes from Carmona et al. (2021) and is available in the Figshare repository: <https://doi.org/10.6084/m9.figshare.13140146>.

Human research participants

Policy information about [studies involving human research participants and Sex and Gender in Research](#).

Reporting on sex and gender	<i>Use the terms sex (biological attribute) and gender (shaped by social and cultural circumstances) carefully in order to avoid confusing both terms. Indicate if findings apply to only one sex or gender; describe whether sex and gender were considered in study design whether sex and/or gender was determined based on self-reporting or assigned and methods used. Provide in the source data disaggregated sex and gender data where this information has been collected, and consent has been obtained for sharing of individual-level data; provide overall numbers in this Reporting Summary. Please state if this information has not been collected. Report sex- and gender-based analyses where performed, justify reasons for lack of sex- and gender-based analysis.</i>
Population characteristics	<i>Describe the covariate-relevant population characteristics of the human research participants (e.g. age, genotypic information, past and current diagnosis and treatment categories). If you filled out the behavioural & social sciences study design questions and have nothing to add here, write "See above."</i>
Recruitment	<i>Describe how participants were recruited. Outline any potential self-selection bias or other biases that may be present and how these are likely to impact results.</i>
Ethics oversight	<i>Identify the organization(s) that approved the study protocol.</i>

Note that full information on the approval of the study protocol must also be provided in the manuscript.

Field-specific reporting

Please select the one below that is the best fit for your research. If you are not sure, read the appropriate sections before making your selection.

Ecological, evolutionary & environmental sciences study design

All studies must disclose on these points even when the disclosure is negative.

Study description	This study is a reply to a comment (Weigelt et al.) to a published paper (Carmona et al. 2021, Nature). The comment argued the points raised by Carmona et al. (2021) miss to account for the appropriate methodological approach. We demonstrate that our original analyses were correct and suggest an accurate procedure to avoid misunderstandings in the future. In particular, we demonstrate that to assess the relationship among functional traits in a PCA-based space it is required to account for all significant dimensions, which can be done by estimating the angles among traits.
Research sample	This reply is based on plant functional trait data for aboveground (leaf area, leaf nitrogen content, specific leaf area, seed mass, specific stem density, plant height and specific leaf area, while for below-ground fine-root traits we used; specific root length, root nitrogen, root diameter, and root tissue density. All data was published before in the original paper published in Nature.
Sampling strategy	The sample size of the analyses is 301 plant species, where there are measurements for all traits explained before.
Data collection	Data was compiled from online databases and published papers, compiled by Riin Tamme.
Timing and spatial scale	We did not restrict the data to any time or space frame, as our aim was to describe the global pattern of plant form and function, including belowground information.
Data exclusions	Species with incomplete data (for any of the traits used) were excluded from the analyses, similarly as done in Carmona et al. 2021 (Nature).
Reproducibility	This is an observational study so experimental reproducibility is not applicable.
Randomization	We did not use randomization in this reply as we only tested the effects of PCA varimax rotation in relation to the angles of the traits and PCA axes.
Blinding	We did not used blinding, as the analyses performed was based on testing the angles of the traits use in the functional spaces derived from PCA analyses only.
Did the study involve field work?	<input type="checkbox"/> Yes <input checked="" type="checkbox"/> No

Reporting for specific materials, systems and methods

We require information from authors about some types of materials, experimental systems and methods used in many studies. Here, indicate whether each material, system or method listed is relevant to your study. If you are not sure if a list item applies to your research, read the appropriate section before selecting a response.

Materials & experimental systems

n/a	Involvement in the study
<input checked="" type="checkbox"/>	<input type="checkbox"/> Antibodies
<input checked="" type="checkbox"/>	<input type="checkbox"/> Eukaryotic cell lines
